Part 1: The Original Study

1.1 Exploring the Experiment

```r
library(tidyverse)
```

```
## -- Attaching core tidyverse packages ------------------------ tidyverse 2.0.0 --
## v dplyr     1.2.0     v readr     2.1.6
## v forcats   1.0.1     v stringr   1.5.1
## v ggplot2   4.0.2     v tibble    3.3.1
## v lubridate 1.9.5     v tidyr     1.3.2
## v purrr     1.2.1
## -- Conflicts ------------------------------------------ tidyverse_conflicts() --
## x dplyr::filter() masks stats::filter()
## x dplyr::lag()    masks stats::lag()
## i Use the conflicted package (<http://conflicted.r-lib.org/>) to force all conflicts to become errors
```

```r
gay <- read_csv("data/raw/gay.csv")
```

```
## Rows: 69592 Columns: 4
## -- Column specification --------------------------------------------------------
## Delimiter: ","
## chr (1): treatment
## dbl (3): study, wave, ssm
##
## i Use `spec()` to retrieve the full column specification for this data.
## i Specify the column types or set `show_col_types = FALSE` to quiet this message.
```

Q1.1

```r
dim(gay)
```

```
## [1] 69592     4
```

```r
table(gay$study)
```

```
##
##     1     2
## 59207 10385
```

```r
table(gay$treatment)
```

```
##
##                                        No Contact
##                                             37735
##                 Recycling Script by Gay Canvasser
##                                              6514
##            Recycling Script by Straight Canvasser
##                                              6474
##         Same-Sex Marriage Script by Gay Canvasser
##                                             12452
## Same-Sex Marriage Script by Straight Canvasser
##                                              6417
```

The dataset contains 69,592 total observations, and the variable `study` takes on 2 unique values, `1` and `2`.

There are 5 treatment conditions:

1. No Contact
2. Recycling Script by Gay Canvasser
3. Recycling Script by Straight Canvasser
4. Same-Sex Marriage Script by Gay Canvasser
5. Same-Sex Marriage Script by Straight Canvasser

Q1.2

```r
gaystudy1wave1 <- gay[(gay$study == 1) & (gay$wave == 1),]
summarize(group_by(gaystudy1wave1, treatment), mean(ssm), length(ssm))
```

```
## # A tibble: 5 x 3
##   treatment                                        `mean(ssm)` `length(ssm)`
##   <chr>                                                  <dbl>         <int>
## 1 No Contact                                              3.04          5238
## 2 Recycling Script by Gay Canvasser                       3.13          1046
## 3 Recycling Script by Straight Canvasser                  3.01          1039
## 4 Same-Sex Marriage Script by Gay Canvasser               3.03          1151
## 5 Same-Sex Marriage Script by Straight Canvasser          3.10          1033
```

The Recycling Script by Gay Canvasser treatment shows the highest average support, with a mean `ssm` of 3.130975.

Q1.3

```r
summarize(group_by(gaystudy1wave1, treatment), sd(ssm))
```

```
## # A tibble: 5 x 2
##   treatment                                        `sd(ssm)`
##   <chr>                                                <dbl>
## 1 No Contact                                            1.68
## 2 Recycling Script by Gay Canvasser                     1.70
## 3 Recycling Script by Straight Canvasser                1.68
## 4 Same-Sex Marriage Script by Gay Canvasser             1.67
## 5 Same-Sex Marriage Script by Straight Canvasser        1.68
```

The standard deviations are roughly similar across all treatment groups, around 1.68. Similar standard deviations are important in a randomized experiment because they indicate similar variation and shape of the sampling distribution across treatment groups. No treatment group had abnormally varied effects that might suggest that variables other than the treatment might be confounding the relationship and causing additional variation.

Q1.4

```
ggplot(summarize(group_by(gaystudy1wave1, treatment), mean_ssm = mean(ssm)), aes(x = mean_ssm, y = trea
  geom_col(stat = "identity", color = "black", fill = "white") +
  labs(title = "Study 1 Baseline Attitudes Toward Same-Sex Marriage",
       x = "Mean Feeling Thermometer for Same-Sex Marriage",
       y = "Treatment Group")
```

1.2 Checking Balance and Comparing Outcomes

Q1.5

From Q1.2 and Q1.3, we have:

```
gaystudy1wave1_treatmentmean <- mean(gaystudy1wave1$ssm[gaystudy1wave1$treatment == "Same-Sex Marriage S
gaystudy1wave1_treatmentsd <- sd(gaystudy1wave1$ssm[gaystudy1wave1$treatment == "Same-Sex Marriage Scri
gaystudy1wave1_controlmean <- mean(gaystudy1wave1$ssm[gaystudy1wave1$treatment == "No Contact"])
gaystudy1wave1_controlsd <- sd(gaystudy1wave1$ssm[gaystudy1wave1$treatment == "No Contact"])
```

```
gaystudy1wave1_treatmentmean
```

```
## [1] 3.025195
```

```
gaystudy1wave1_treatmentsd
```

```
## [1] 1.666099
```

```
gaystudy1wave1_controlmean
```

```
## [1] 3.042764
```

```
gaystudy1wave1_controlsd
```

```
## [1] 1.68054
```

```
(gaystudy1wave1_treatmentmean - gaystudy1wave1_controlmean)/sqrt(((gaystudy1wave1_treatmentsd)^2+(gaystu
```

```
## [1] -0.01049935
```

Yes, these groups look similar at baseline. Their standardized difference, -0.01049935, is below 0.25 in absolute value.

Q1.6

```
gaystudy1wave2 <- gay[(gay$study == 1) & (gay$wave == 2),]
gaystudy1wave2_treatmentmean <- mean(gaystudy1wave2$ssm[gaystudy1wave2$treatment == "Same-Sex Marriage S
gaystudy1wave2_controlmean <- mean(gaystudy1wave2$ssm[gaystudy1wave2$treatment == "No Contact"])

gaystudy1wave2_treatmentmean
```

```
## [1] 3.139489
```

```
gaystudy1wave2_controlmean
```

```
## [1] 3.039615
```

```
gaystudy1wave2_treatmentmean-gaystudy1wave2_controlmean
```

```
## [1] 0.09987463
```

The difference in means is positive 0.09987463. Since the groups were balanced at baseline, this difference at Wave 2 suggests that the treatment has had some, albeit very small, effect in improving the treatment group's attitudes toward same-sex marriage compared to the control group.

Part 2: The Forensic Discovery

2.1 The Baseline Distribution

Q2.1

```r
gay_r <- read_csv("data/raw/gayreshaped.csv")
```

```
## Rows: 11948 Columns: 6
## -- Column specification --------------------------------------------------------
## Delimiter: ","
## chr (1): treatment
## dbl (5): study, therm1, therm2, therm3, therm4
##
## i Use `spec()` to retrieve the full column specification for this data.
## i Specify the column types or set `show_col_types = FALSE` to quiet this message.
```

```r
ccap <- read_csv("data/raw/ccap2012.csv")
```

```
## New names:
## Rows: 43998 Columns: 3
## -- Column specification
## -------------------------------------------------------- Delimiter: "," dbl
## (3): ...1, caseid, gaytherm
## i Use `spec()` to retrieve the full column specification for this data. i
## Specify the column types or set `show_col_types = FALSE` to quiet this message.
## * `` -> `...1`
```

```r
dim(gay_r)
```

```
## [1] 11948     6
```

```r
dim(ccap)
```

```
## [1] 43998     3
```

```r
colnames(gay_r)
```

```
## [1] "study"     "treatment" "therm1"    "therm2"    "therm3"    "therm4"
```

```r
colnames(ccap)
```

```
## [1] "...1"     "caseid"   "gaytherm"
```

The dataset `gay_r` has 11948 observations for 6 columns `study`, `treatment`, `therm1`, `therm2`, `therm3`, and `therm4`.

The dataset `ccap` has 43998 observations for 3 columns `caseid`, `gaytherm`, and a blank column for the observation number.

Q2.2

```r
study1_therm1 <- c(gay_r[gay_r$study == 1,]$therm1)

mean(study1_therm1)
```

```
## [1] 58.37625
```

```r
median(study1_therm1)
```

```
## [1] 52
```

```r
sd(study1_therm1)
```

```
## [1] 28.50288
```

```r
ccap_gaytherm <- c(ccap$gaytherm)

mean(ccap_gaytherm, na.rm = TRUE)
```

```
## [1] 58.70517
```

```r
median(ccap_gaytherm, na.rm = TRUE)
```

```
## [1] 54
```

```r
sd(ccap_gaytherm, na.rm = TRUE)
```

```
## [1] 29.36892
```

For `gay_r` and `ccap`, respectively, the feeling thermometer statistics are:

Means: 58.37625, 58.70517

Medians: 52, 54

Standard deviations: 28.50288, 29.36892

All 3 statistics are strikingly similar. The means differ by less than 0.4, the medians differ by 2, and the standard deviations differ by less than 1. This level of similarity suggests that there might be some overlap in the data itself.

Q2.3

```r
study1_baselinetherm <- gay_r[gay_r$study == 1,] %>%
  rename(therm = therm1) %>%
  mutate(source = "LaCour")

ccap_therm <- ccap %>%
  rename(therm = gaytherm) %>%
  mutate(source = "CCAP")

lacour_ccap <- bind_rows(study1_baselinetherm, ccap_therm)

ggplot(lacour_ccap, aes(x = therm)) +
  geom_histogram(breaks = seq(0, 100, by = 5), color = "black", fill = "white") +
  facet_wrap(~source) +
  labs(title = "CCAP and LaCour Study 1 Baseline Therms",
       x = "Feeling Thermometer for Same-Sex Marriage (0-100)",
       y = "Count")
```

```
## Warning: Removed 3097 rows containing non-finite outside the scale range
## (`stat_bin()`).
```

The two datasets do not appear to have come from different populations. The shape of the distribution is almost exactly mirrored in LaCour's data, with the main difference being the sample size. There are noticeable peaks at 0, 50, and 100 in both datasets, which is to be expected due to heaping, but the distribution in between those values is also highly similar in terms of shape and relative proportions.

2.2 Re-test Reliability

Q2.4

```
study1_control <- gay_r[(gay_r$treatment == "No Contact") & (gay_r$study == 1),]
cor(study1_control$therm1, study1_control$therm2, use = "complete.obs")
```

```
## [1] 0.9975817
```

```
sd(study1_control$therm2 - study1_control$therm1, na.rm = TRUE)
```

```
## [1] 1.987678
```

```
study2_control <- gay_r[(gay_r$treatment == "No Contact") & (gay_r$study == 2),]
cor(study2_control$therm1, study2_control$therm2, use = "complete.obs")
```

```
## [1] 0.9734449
```

```
sd(study2_control$therm2 - study2_control$therm1, na.rm = TRUE)
```

```
## [1] 6.605738
```

Study 2 shows a more plausible pattern with a correlation of 0.9734449 in the re-test data and a standard deviation of 6.605738, matching a reasonable re-test correlation in the range of 0.95-0.97 and substantial variability. On the other hand, Study 1 has a suspiciously high correlation of 0.9975817 and a low standard deviation of 1.987678, making it unlikely to have drawn from data with real people who change their minds. Thus, Study 2 more accurately reflects real-world changes in individuals' feelings between re-testing.

Q2.5

```
plot(therm2 ~ therm1, data = study1_control)
abline(a = 0, b = 1, col = "red")
```

```r
plot(therm2 ~ therm1, data = study2_control)
abline(a = 0, b = 1, col = "red")
```

Study 2 looks more like real longitudinal data than Study 1. The data for Study 1 lies exactly on the 45-degree line except for around 0, 50, and 100, which suggests an unrealistic assumption that the majority of people's feeling thermometers are entirely constant between the two tests. On the other hand, the data for Study 2 is scattered around the line and demonstrates more realistic variability in the two thermometer measurements for each individual. Additionally, the data for Study 2 demonstrates more realistic distributions of data points around 0, 50, and 100, while the data for Study 1 shows only horizontal distributions at these points, suggesting that the data might have artificially attempted to create variation at these values.

2.3 Putting It All Together

Q2.6

The findings suggest that the data was fabricated rather than collected because they match the properties of computer-generated data. Specifically, the similar baseline distributions between the study data and CCAP data, including the observation that their means are only 0.4 apart and standard deviations are less than 1 apart, suggest that a computer may have drawn on the CCAP data for the baseline. For the second wave, the computer seems to have replicated the baseline data with some slight modifications given the extremely high re-test correlation of 0.9975817 and the scatterplot displaying near-identical measurements between the two thermometers. Also, the standard deviation of 1.987678 in the within-person changes in thermometers resembles the 95% interval for a normal distribution of 1.96 standard deviations, suggesting that a computer artificially adjusted the data to resemble a normal distribution, which matches the horizontally adjusted values at `therm1` values of 0, 50, and 100 in the scatterplot.

3 Part 3: What Real Data Looks Like

3.1 Comparing Baselines

Q3.1

```
study2 = gay_r[gay_r$study == 2,]
dim(study2)
```

```
## [1] 2441    6
```

```
dim(study2[study2$treatment == "No Contact",])
```

```
## [1] 1203    6
```

```
dim(study2[study2$treatment == "Same-Sex Marriage Script by Gay Canvasser",])
```

```
## [1] 1238    6
```

```
mean(study2[study2$treatment == "No Contact",]$therm1)
```

```
## [1] 57.88612
```

```
sd(study2[study2$treatment == "No Contact",]$therm1)
```

```
## [1] 28.69655
```

```
mean(study2[study2$treatment == "Same-Sex Marriage Script by Gay Canvasser",]$therm1)
```

```
## [1] 59.35057
```

```
sd(study2[study2$treatment == "Same-Sex Marriage Script by Gay Canvasser",]$therm1)
```

```
## [1] 28.41578
```

Study 2 contains 2441 observations, with 1203 from the control group and 1238 from the treatment group. The mean and SD of `therm1` for the control group are 57.88612 and 28.69655, respectively. The mean and SD of `therm1` for the treatment group are 59.35057 and 28.41578, respectively.

Q3.2

```r
study1_baselinetherm <- gay_r[gay_r$study == 1,] %>%
  rename(therm = therm1) %>%
  mutate(source = "Study 1")
study2_baselinetherm <- gay_r[gay_r$study == 2,] %>%
  rename(therm = therm1) %>%
  mutate(source = "Study 2")

study1_study2 <- bind_rows(study1_baselinetherm, study2_baselinetherm)

ggplot(study1_study2, aes(x = therm)) +
  geom_histogram(breaks = seq(0, 100, by = 5), color = "black", fill = "white") +
  facet_wrap(~source) +
  labs(title = "Study 1 and Study 2 Baseline Therms",
       x = "Feeling Thermometer for Same-Sex Marriage (0-100)",
       y = "Count")
```

The two datasets still appear to have come from similar populations, since the shapes of the distributions are still extremely similar. As before, both datasets still have modes around 50, 0, and 100.

3.2 Checking Balance and Comparing Outcomes in Study 2

Q3.3

From Q3.1, we have:

```
controlbaseline_mean <- mean(study2[study2$treatment == "No Contact",]$therm1)
controlbaseline_sd <- sd(study2[study2$treatment == "No Contact",]$therm1)
treatmentbaseline_mean <- mean(study2[study2$treatment == "Same-Sex Marriage Script by Gay Canvasser",]$
treatmentbaseline_sd <- sd(study2[study2$treatment == "Same-Sex Marriage Script by Gay Canvasser",]$ther

controlbaseline_mean
```

```
## [1] 57.88612
```

```
controlbaseline_sd
```

```
## [1] 28.69655
```

```
treatmentbaseline_mean
```

```
## [1] 59.35057
```

```
treatmentbaseline_sd
```

```
## [1] 28.41578
```

```
(treatmentbaseline_mean - controlbaseline_mean)/sqrt(((treatmentbaseline_sd)^2+(controlbaseline_sd)^2)/
```

```
## [1] 0.05128243
```

Yes, these groups look similar at baseline. Their standardized difference, 0.05128243, is below 0.25 in absolute value.

Q3.4

```
controlpost_mean <- mean(study2[study2$treatment == "No Contact",]$therm2, na.rm = TRUE)
treatmentpost_mean <- mean(study2[study2$treatment == "Same-Sex Marriage Script by Gay Canvasser",]$ther

controlpost_mean
```

```
## [1] 57.63523
```

```
treatmentpost_mean
```

```
## [1] 61.20311
```

```
treatmentpost_mean - controlpost_mean
```

```
## [1] 3.567885
```

The difference in means is positive 3.567885. Since the groups were balanced at baseline, this difference suggests that the treatment has had an effect in improving the treatment group's attitudes toward same-sex marriage compared to the control group.

3.3 Uncertainty Around the Difference

Q3.5

```
controlpost_sd <- sd(study2[study2$treatment == "No Contact",]$therm2, na.rm = TRUE)
treatmentpost_sd <- sd(study2[study2$treatment == "Same-Sex Marriage Script by Gay Canvasser",]$therm2,

controlpost_obs <- length(study2[study2$treatment == "No Contact",]$therm2) - sum(is.na(study2[study2$t
treatmentpost_obs <- length(study2[study2$treatment == "Same-Sex Marriage Script by Gay Canvasser",]$th

SEpost <- sqrt((treatmentpost_sd)^2/treatmentpost_obs + (controlpost_sd)^2/controlpost_obs)

SEpost
```

```
## [1] 1.242138
```

```
(treatmentpost_mean - controlpost_mean) - 1.96*SEpost
```

```
## [1] 1.133294
```

```
(treatmentpost_mean - controlpost_mean) + 1.96*SEpost
```

```
## [1] 6.002475
```

The standard error is 1.242138, and the 95% confidence interval is (1.133294, 6.002475). The confidence interval does not include 0, which suggests that we can reject the null hypothesis and conclude there is a statistically significant positive difference between the treatment group and control group post-conversation.

3.4 Tracking Attitudes Over Time

Q3.6

```
cor(study2[study2$treatment == "No Contact",]$therm1, study2[study2$treatment == "No Contact",]$therm2,
```

```
## [1] 0.9734449
```

```
cor(study2[study2$treatment == "No Contact",]$therm1, study2[study2$treatment == "No Contact",]$therm3,
```

```
## [1] 0.9594085
```

```
cor(study2[study2$treatment == "No Contact",]$therm1, study2[study2$treatment == "No Contact",]$therm4,
```

```
## [1] 0.9709017
```

The correlations do not necessarily steadily decay over time but do fluctuate within/around the reasonable range of 0.95-0.97, suggesting that real survey display variation from shifts in feeling thermometers between measurements and are not completely stable.

Q3.7

Although both studies had similar baseline distributions, Study 2 better represents realistic data. Study 2 has lower correlations between waves, with a maximum between-thermometer correlation of 0.9734449 compared to the between-thermometer correlation of 0.9975817 for Study 1, suggesting that Study 2 more accurately captures the variation and instability in real survey measurements. This comparison is further supported by Study 2's between-thermometer scatterplot with greater variability, along with a standard deviation of 6.605738 that is much higher than the low standard deviation of 1.987678 of Study 1. The real treatment effects are thus smaller and messier than fabricated ones because real people do not respond to feeling thermometers like computers, which generate clean data; real people will demonstrate greater fluctuations and variability in their feeling thermometers between measurements, creating more inconsistent means, higher standard deviations, histograms/scatterplots with higher variance, and lower correlations than fabricated data.

Part 4: Formalizing the Evidence with Regression

4.1 Regression as a Fraud Detector

Q4.1

```r
fit_s1 <- lm(therm2 ~ therm1, data = gay_r[(gay_r$study == 1) & (gay_r$treatment == "No Contact"),])
summary(fit_s1)
```

```
##
## Call:
## lm(formula = therm2 ~ therm1, data = gay_r[(gay_r$study == 1) &
##     (gay_r$treatment == "No Contact"), ])
##
## Residuals:
##      Min       1Q   Median       3Q      Max
## -15.8631  -0.1121   0.1746   0.4312  10.1369
##
## Coefficients:
##             Estimate Std. Error t value Pr(>|t|)
## (Intercept) 0.240430   0.066000   3.643 0.000273 ***
## therm1      0.992454   0.001012 980.624  < 2e-16 ***
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 1.976 on 4668 degrees of freedom
##   (568 observations deleted due to missingness)
## Multiple R-squared:  0.9952, Adjusted R-squared:  0.9952
## F-statistic: 9.616e+05 on 1 and 4668 DF,  p-value: < 2.2e-16
```

The slope, $\hat{\beta}_1$, is 0.992454, which indicates that every increase of 1 in `therm1` is associated with an increase of 0.992454 in `therm2`. The R-squared is 0.9952, which indicates that the model explains 99.52% of the variability of `therm2`. The residual standard error is 1.976.

Q4.2

```r
fit_s2 <- lm(therm2 ~ therm1, data = study2[study2$treatment == "No Contact",])
summary(fit_s2)
```

```
##
## Call:
## lm(formula = therm2 ~ therm1, data = study2[study2$treatment ==
##     "No Contact", ])
##
## Residuals:
##      Min       1Q   Median       3Q      Max
## -22.7102  -3.4793   0.0363   3.5092  22.8455

## F-statistic: 1.875e+04 on 1 and 1037 DF,  p-value: < 2.2e-16
```

The slope, $\hat{\beta}_1$, is 0.968662, which indicates that every increase of 1 in `therm1` is associated with an increase of 0.968662 in `therm2`. The R-squared is 0.9476, which indicates that the model explains 94.76% of the variability of `therm2`. The residual standard error is 6.547.

Comparing the two models, Study 2 has a lower and more realistic value for $\hat{\beta}_1$ of 0.968662 (< 1) compared to 0.992454 (≈ 1) for Study 1. Similarly, the Study 2 R-squared of 0.9476 is lower and more realistic compared to the Study 1 R-squared of 0.9476. Thus, Study 1 resembles fabricated data that duplicates the baseline between waves, resulting in an abnormally high slope coefficient and explanation of variability (R-squared), while Study 2 resembles real data that displays some regression to the mean and slightly lower explanation of variability.

4.2 Comparing Groups with Regression

Q4.3

```r
study2_treatmentcontrol <- study2[study2$treatment == "Same-Sex Marriage Script by Gay Canvasser" | stu

treated <- ifelse(study2_treatmentcontrol$treatment == "Same-Sex Marriage Script by Gay Canvasser", 1, 

study2_treatmentcontrol <- mutate(study2_treatmentcontrol, treated = treated)

fit_treated <- lm(therm2 ~ treated, data = study2_treatmentcontrol)
summary(fit_treated)
```

```
##
## Call:
## lm(formula = therm2 ~ treated, data = study2_treatmentcontrol)
##
## Residuals:
##     Min      1Q  Median      3Q     Max
## -61.203 -15.635  -3.203  24.365  42.365
##
## Coefficients:
##             Estimate Std. Error t value Pr(>|t|)
## (Intercept)  57.6352     0.8895  64.794  < 2e-16 ***
## treated       3.5679     1.2423   2.872  0.00412 **
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 28.67 on 2130 degrees of freedom
##   (309 observations deleted due to missingness)
## Multiple R-squared:  0.003857,   Adjusted R-squared:  0.00339
## F-statistic: 8.248 on 1 and 2130 DF,  p-value: 0.00412
```

The slope, $\hat{\beta}_1$, is 3.5679, which indicates that the mean `therm2` of the treatment group is 3.5679 higher than the mean `therm2` of the control group. This value matches the calculated difference in means of 3.567885 from Q3.4. The standard error, t-statistic, and p-value for $\hat{\beta}_1$ are 1.2423, 2.872, and 0.00412, respectively, so the difference between the two groups, is statistically significant at the $\alpha = 0.05$ level since $p < 0.05$. $\hat{\beta}_0$ estimates the mean `therm2` of the control group, or 57.6352, which also matches the calculated control group mean of 57.63523 from Q3.4.

4.3 Controlling for Baseline Attitudes

Q4.4

```r
fit_treatedtherm1 <- lm(therm2 ~ treated + therm1, data = study2_treatmentcontrol)
summary(fit_treatedtherm1)
```

```
##
## Call:
## lm(formula = therm2 ~ treated + therm1, data = study2_treatmentcontrol)
##
## Residuals:
##     Min      1Q  Median      3Q     Max
## -27.194  -4.476  -0.476   3.688  35.558
##
## Coefficients:
##             Estimate Std. Error t value Pr(>|t|)
## (Intercept) 1.727135   0.423275    4.08 4.66e-05 ***
## treated     2.458857   0.341052    7.21 7.76e-13 ***
## therm1      0.965808   0.005973  161.69  < 2e-16 ***
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 7.87 on 2129 degrees of freedom
```

```
##   (309 observations deleted due to missingness)
## Multiple R-squared:  0.925,  Adjusted R-squared:  0.9249
## F-statistic: 1.313e+04 on 2 and 2129 DF,  p-value: < 2.2e-16
```

The coefficient on `treated` is 2.458857, with a standard error of 0.341052, a t-statistic of 7.21, and a p-value of virtually 0.

(a) The estimate of $\hat{\beta}_1$ decreased (but not drastically) from 3.5679 to 2.458857.
(b) The standard error decreased significantly from 1.2423 to 0.341, a decrease of 72.55091%, and the p-value also decreased significantly from (the already statistically significant) 0.00412 to virtually 0.
(c) Controlling for baseline attitudes improves precision by accounting for an additional explanatory variable for `therm2` so that the direct effect of `treated` on `therm2` can be isolated. We found in Q4.2 that there is a strong association between the value of `therm1` and the value of `therm2`, so controlling for `therm1` allows us to "hone in" on the effects of `treated` on `therm2`.

Q4.5

The R-squared value increases from 0.003857 to 0.925. Adding `therm1` creates this dramatic increase in R-squared because it explains a large portion of the variability in `therm2`, which indicates that the vast majority of the variation in follow-up attitudes is better explained by where people started compared to the treatment itself.

```r
personA <- data.frame(treated = 1, therm1 = 50)
personB <- data.frame(treated = 0, therm1 = 50)
predict(fit_treatedtherm1, personA)
```

```
##        1
## 52.47638
```

```r
predict(fit_treatedtherm1, personB)
```

```
##        1
## 50.01752
```

```r
predict(fit_treatedtherm1, personA) - predict(fit_treatedtherm1, personB)
```

```
##        1
## 2.458857
```

The predicted difference in Wave 2 attitudes is 2.458857, consistent with the slope coefficient of the model.
